# Dispositions

## Max-Flow

1. (Define a Flow Network)
  - (Capacity Constraint)
  - (Flow Conservation)
2. Define a Max Flow
3. (How to have multiple source/sink networks)
4. (Introduce Residual Networks)
5. (Introduce Augmenting Paths)
6. Cuts - In particular the min cut max flow
7. Introduce Ford-Fulkerson / Edmonds-Karp

## Fibonacci Heaps

1. Mergeable heaps
2. Structure
3. Operations
  - Make-Heap
  - Insert
  - ExtractMin
  - Union/Merge
  - DecreaseKey
  - Delete

Write something about  $D(n)$  since it's used for all the proofs.

## **NP-Completeness**

1. Polynomial time vs Superpolynomial time
2. P-Class problems
3. NP-Class problems
4. Decisions vs Optimization problems
5. Reductions and verifiability/certificates
6. P vs NP vs NPC

## **Randomized Algorithms**

1. Las-Vegas vs. Monte Carlo Algorithms
2. Decision Monte Carlo, one sided vs. two sided error.
3. Bounding Runningtimes
4. Markov & Chebyshev's inequalities
5. Randomized Quicksort
6. (Randomized Selection)

## **Hashing**

### **1. WHOOP**

## **Exact Exponential Algorithms & Fixed-parameter tractable problems**

1.  $O^*$ -notation
2. Parameterized Complexity
3. Travelling Salesman Problem using Dynamic Programming
4. CNF-Satisfiability.
5. I DON'T KNOW WHAT TO DO!?

## **Approximation Algorithms**

1. Performance Ratios
2. Approximation Schemes
3. Vertex Cover example

## **Computational Geometry**

### **1. WHOOP**

## **Linear Programming and Optimization**

### **1. WHOOP**

# Notes

## Max-Flow

### Flow Network

A flow network  $G = (V, E)$  is a directed graph where each edge  $(u, v) \in E$  have a nonnegative capacity  $c(u, v) \geq 0$ . In addition, for any edge  $(u, v)$  there can be no antiparallel edge  $(v, u)$ .

Two vertices in the network have special characteristics the source  $s$  and sink  $t$ . We assume each vertex  $v \in V$  lies on some path from  $s$  to  $t$ , that is, for each vertex  $v \in V$ , the flow network contains a path  $s \rightsquigarrow v \rightsquigarrow t$ .

### Flow Definition

We have a flow network  $G = (V, E)$  with a source  $s$  and a sink  $t$ , the network has a capacity function  $c(u, v)$ . A flow is a real-valued function  $f : V \times V \rightarrow \mathbb{R}$  that satisfies the two following properties:

- **Capacity Constraint:**

For all  $u, v \in V$ , we require  $0 \leq f(u, v) \leq c(u, v)$

- **Flow Conservation:**

For all  $u \in V - \{s, t\}$  we require

$$\sum_{v \in V} f(v, u) = \sum_{v \in V} f(u, v)$$

When  $(u, v) \notin E$ , there can be no flow from  $u$  to  $v$ , and  $f(u, v) = 0$ . We call the nonnegative quantity  $f(u, v)$  the flow from vertex  $u$  to vertex  $v$ .

The value  $|f|$  of a flow  $f$  is defined as

$$|f| = \sum_{v \in V} f(s, v) - \sum_{v \in V} f(v, s)$$

that is the total flow out of the source minus the flow into the source. For an example of a flow see Figure 1

## Antiparallel Edges and Multiple Sources/Sinks

Since a flow network cannot contain anti-parallel edges, but we want to be able to represent them in our graph, we need a way to do so. This is done by inserting an additional node  $v'$  and let one of the edges go through this node instead, see Figure 2 for an example.

If a network have multiple sources or sinks, we can convert it to a single source/sink network by adding a supersource and supersink. An example of such conversion can be seen in Figure 3.

## Flow Examples

Figure 1: Example flow.

Figure 2: Conversion from antiparallel edges to proper flow.

Figure 3: Example of a graph with multiple sources and sink, combined using a supersource and supersink.

### Residual Networks

Given a flow network  $G$  and a flow  $f$  the residual network  $G_f$  consists of edges and capacities that represent how we can change the flow on edges of  $G$ . Suppose we have a flow network  $G = (V, E)$  with source  $s$  and sink  $t$ . Let  $f$  be a flow in  $G$ , and consider a pair of vertices  $u, v \in V$ . We then define the residual capacity  $c_f(u, v)$  like this:

$$c_f(u, v) = \begin{cases} c(u, v) - f(u, v) & \text{if } (u, v) \in E, \\ f(v, u) & \text{if } (v, u) \in E, \\ 0 & \text{otherwise.} \end{cases}$$

Given a flow network  $G = (V, E)$  and a flow  $f$ , the residual network of  $G$  induced by  $f$  is  $G_f(V, E_f)$ , where

$$E_f = \{(u, v) \in V \times V : c_f(u, v) > 0\}$$

An example of a residual network can be seen in Figure 4.

Figure 4: An example of a flow being augmented and showing the residual graph.

### Augmenting Flows

Augmenting paths are simply flows that can be added to other flows in order to increase the flow value through the network. Augmenting flows are described using the  $\uparrow$  operator like so:

$$(f \uparrow f')(u, v) = \begin{cases} f(u, v) + f'(u, v) - f'(v, u) & \text{if } (u, v) \in E, \\ 0 & \text{otherwise.} \end{cases}$$

an example of an applied augmenting path can be seen in Figure 4.

**Lemma 26.1** Let  $G = (V, E)$  be a flow network with source  $s$  and sink  $t$ , and let  $f$  be a flow in  $G$ . Let  $G_f$  be the residual network of  $G$  induced by  $f$ , and let  $f'$  be a flow in  $G_f$ . Then the function  $f \uparrow f'$  is a flow in  $G$  with value  $|f \uparrow f'| = |f| + |f'|$ .

### Augmenting Paths

Given a network  $G = (V, E)$  and a flow  $f$ , an augmenting path is a simple path from  $s$  to  $t$  in the residual network  $G_f$ . The shaded path in Figure 4(b) is an augmenting path. We can increase the flow on each edge in the augmenting

path  $p$  by an amount equal to the residual capacity of  $p$  given by

$$c_f(p) = \min\{c_f(u, v) : (u, v) \text{ is on } p\}$$

That is, the smallest amount of spare capacity on any edge in  $p$ .

**Lemma 26.2** let  $G = (V, E)$  be a flownetwork, let  $f$  be a flow in  $G$ , and let  $p$  be an augmenting path in  $G_f$ . Define a function  $f_p : V \times V \rightarrow \mathbb{R}$  by

$$f_p(u, v) = \begin{cases} c_f(p) & \text{if } (u, v) \text{ is on } p, \\ 0 & \text{otherwise.} \end{cases}$$

Then,  $f_p$  is flow in  $G_f$  with value  $|f_p| = c_f(p) > 0$ .

**Corollary 26.3** let  $G = (V, E)$  be a flownetwork, let  $f$  be a flow in  $G$ , and let  $p$  be an augmenting path in  $G_f$ . Let  $f_p$  be defined as in Lemma 26.2, and suppose that we augment  $f$  by  $f_p$ . Then the function  $f \uparrow f'$  is a flow in  $G$  with value  $|f \uparrow f'| = |f| + |f_p| > |f|$ .

### Cuts in flow networks

A cut  $(S, T)$  of a flow network  $G = (V, E)$  is a partition of  $V$  into  $S$  and  $T = V - S$  such that  $s \in S$  and  $t \in T$ . If  $f$  is a flow, then the net flow  $f(S, T)$  across the cut  $(S, T)$  is defined to be

$$f(S, T) = \sum_{u \in S} \sum_{v \in T} f(u, v) - \sum_{u \in S} \sum_{v \in T} f(v, u).$$

The capacity of the cut  $(S, T)$  is

$$c(S, T) = \sum_{u \in S} \sum_{v \in T} c(u, v).$$

A **minimum cut** of a network is a cut whose capacity is minimum over all cuts of the network. Note that for capacity we count only edges going from  $S$  to  $T$  while for flow we count edges going both directions. Lemma 26.4 shows that for a given flow  $f$ , the net flow across any cut is the same and it equals  $|f|$ , the value of the flow.

**Lemma 26.4** Let  $f$  be a flow in a flow network  $G = (V, E)$  with source  $s$  and sink  $t$ , and let  $(S, T)$  be any cut of  $G$ . Then the net flow across  $(S, T)$  is  $f(S, T) = |f|$

**Corollary 26.5** The value of any flow  $f$  in a flow network  $G$  is bounded from above by the capacity of any cut of  $G$ .

**Max-flow min-cut theorem:**

**Theorem 26.6** If  $f$  is a flow in a flow network  $G = (V, E)$  with source  $s$  and sink  $t$ , then the following conditions are equivalent:

1.  $f$  is a maximum flow in  $G$ .
2. The residual network  $G_f$  contains no augmenting paths.
3.  $|f| = c(S, T)$  for some cut  $(S, T)$  of  $G$ .

**Proof** (1)  $\implies$  (2): If we assume  $f$  is a maximum flow but there still is an augmenting path  $p$  in the residual graph  $G_f$ , then by Corollary 26.3, the flow found by  $f \uparrow f_p$  is a flow with value strictly greater than  $|f|$ , contradicting the assumption that  $f$  is a max flow.

(2)  $\implies$  (3): Suppose  $G_f$  has no augmenting paths, that is, that  $G_f$  contains no paths from  $s$  to  $t$ . We define

$$S = \{v \in V : \text{there exists a path from } s \text{ to } v \text{ in } G_f\}$$

and  $T = V - S$ . The partition  $(S, T)$  is a cut: we have  $s \in S$  trivially, and  $t \notin S$  because there is no path from  $s$  to  $t$  in  $G_f$ .

We now consider a pair of vertices  $u \in S$  and  $v \in T$ . If  $(u, v) \in E$ , we must have  $f(u, v) = c(u, v)$  otherwise  $(u, v) \in E_f$  which would place  $v$  in  $S$ .

If  $(v, u) \in E$ , we must have  $f(v, u) = 0$ , because otherwise  $c_f(u, v) = f(v, u)$  would be positive and we would have  $(u, v) \in E_f$ , which would place  $v$  in  $S$ . If neither  $(u, v)$  or  $(v, u)$  is in  $E$ , then  $f(u, v) = f(v, u) = 0$ . We thus have

$$\begin{aligned} f(S, T) &= \sum_{u \in S} \sum_{v \in T} f(u, v) - \sum_{u \in S} \sum_{v \in T} f(v, u) \\ &= \sum_{u \in S} \sum_{v \in T} c(u, v) - \sum_{u \in S} \sum_{v \in T} 0 \\ &= c(S, T). \end{aligned}$$

By Lemma 26.4, we then have  $|f| = f(S, T) = c(S, T)$ .

(3)  $\implies$  (1): By corollary 26.5,  $|f| \leq c(S, T)$  for all cuts  $(S, T)$ . The condition  $|f| = c(S, T)$  thus implies that  $f$  is a maximum flow.  $\square$

### Ford-Fulkerson

The general algorithm:

FORD-FULKERSON-METHOD( $G, s, t$ )

```
1  initialize flow  $f$  to 0
2  while there exists an augmenting path  $p$  in the residual network  $G_f$ 
3      augment flow  $f$  along  $p$ 
4  return  $f$ 
```

Implementation:

FORD-FULKERSON( $G, s, t$ )

```
1  for each edge  $(u, v) \in G.E$ 
2       $(u, v).f = 0$ 
3  while there exists a path  $p$  from  $s$  to  $t$  in the residual network  $G_f$ 
4       $c_f(p) = \min\{c_f(u, v) : (u, v) \text{ is in } p\}$ 
5      for each edge  $(u, v)$  in  $p$ 
6          if  $(u, v) \in E$ 
7               $(u, v).f = (u, v).f + c_f(p)$ 
8          else  $(v, u).f = (v, u).f - c_f(p)$ 
```

Assume we can pick the path  $p$  in linear time, the loop header is running in  $O(E)$ . If  $f^*$  denote a maximum flow, then the while loop is executed at most  $|f^*|$  times, since each augmentation must increase the flow value with at least one. The for loop inside the loop can be done in  $O(E)$  since the longest  $p$  can be no longer than  $|E|$ . Giving a running time of  $O(|f^*|(E + E)) = O(E|f^*|)$ .

### Edmonds-Karp

Is a Ford-Fulkerson implementation that uses Shortest-Path to find the path  $p$  in line 3 of the Ford-Fulkerson algorithm. Each edge is given unit-weight and

the algorithm will then pick the shortest path each time. It then has a running-time of  $O(VE^2)$ .

**Lemma 26.7** If Edmonds-Karp is run on a flow network  $G = (V, E)$  with source  $s$  and sink  $t$ , then for all vertices  $v \in V - \{s, t\}$ , the shortest-path distance  $\delta_f(s, v)$  in the residual network  $G_f$  increases monotonically with each flow augmentation.

**Proof-ish** Intuitively, if we chose a path  $p$  from  $s \rightarrow v$  that is a shortest path, and then assume there is a path  $p'$  from  $s \rightarrow v$  which is shorter, we contradict our initial statement that  $p$  is a shortest path. This proves that the path length do not decrease.  $p'$  might have the same length as  $p$  or might be longer.  $\square$

**Theorem 26.8** If Edmonds-Karp is run on a flow network  $G = (V, E)$  with source  $s$  and sink  $t$ , then the total number of flow augmentations performed by the algorithm is  $O(VE)$ .

Write down and understand the proof...

## Fibonacci Heaps

Write something about mergable heaps

Fibonacci heaps are a datastructure that supports a set of operations qualifying it as a “meargeable heap”, meaning it supports the following operations.

- `Make-Heap()` Creates and returns a new heap with no elements.
- `Insert(H, x)` Inserts element  $x$  whose key have already been filled in., into heap  $H$ .
- `Minimum(H)` Returns a pointer to the element in heap  $H$  whose key is minimum.
- `Extract-Min(H)` Deletes the element from heap  $H$  whose key is minimum, returning a pointer to the element.
- `Union(H1, H2)` Creates and returns a new heap that contains all the elements of both heaps. Both heaps are destroyed by the operation.

Apart from the meargeable heap operations above, Fibonacci Heaps also support the following two operations.

- `Decrease-Key(H, x, k)` Assigns to element  $x$  in heap  $H$  the new key value  $k$ , which cannot be greater than it's current value.
- `Delete(H, x)` Deletes element  $x$  from  $H$ .

Fibonacci Heaps are by default min-heaps, but could just as well be max heaps, then we would just replace the Minimum, Extract-Min and Decrease-Key operations with Maximum, Extract-Max and Increase-Key instead.

Fibonacci Heaps have a benefit in the fact that many operations are run in constat amortized time. So if these operations are used frequently, the Fibonacci Heap is a well suited structure.

### Structure

A Fibonaccci Heap is a collectoin of rooted trees that are “min-heap ordered”. That is, each tree obeys the minimum-heap property: The key of a node is greater than or equal to the key of its parent. A node  $x$  contains a pointer  $x.p$  to its parent and a pointer  $x.child$  to any one of its children. This list is called the

Procedure	Binary heap(worst case)	Fibonacci heap (amortized)
Make-heap	$\Theta(1)$	$\Theta(1)$
Insert	$\Theta(\lg n)$	$\Theta(1)$
Minimum	$\Theta(1)$	$\Theta(1)$
Extract-Min	$\Theta(\lg n)$	$O(\lg n)$
Union	$\Theta(n)$	$\Theta(1)$
Decrease-Key	$\Theta(\lg n)$	$\Theta(1)$
Delete	$\Theta(\lg n)$	$O(\lg n)$

Table 1: Amortized running times of normal binary heaps and Fibonacci Heaps.

child list. Each node also contains 2 pointers  $x.left$  and  $x.right$ , these points to a nodes siblings or to the node itself if it has no siblings. This forms a circular doubly-linked list called the child list. The nodes may appear in the child list in any order.

Nodes have 2 additional properties,  $x.degree$  which is how many children a node have, and a boolean value  $x.mark$ .  $x.mark$  indicates if  $x$  has lost a child since  $x$  was made the child of another node. Nodes initially have  $x.mark = \text{False}$ .

Figure 5: An example of a Fibonacci Heap with (b) and without (a) the child-list.

We access a fibonacci Heap by the pointer  $H.min$  which points to the root of a tree containing the minimum key, this node is called the minimum node. If there are several nodes with the smallest key, any of those will work. When the heap is empty,  $H.min = NIL$ . The roots of all the tree in a Fibonacci Heap are linked together in a circular doubly-linked list called the “root list”.  $H.min$  points to a node in the root list. The heap also have one other property,  $H.n$  which is the number of nodes currently in  $H$ .

### Operations

**Make-Heap** Simply creates a pointer  $H.min = NIL$ ; since there is no trees in  $H$  at this point. This operation can be performed in  $O(1)$  time.

**Insert** Insertion is done on constant time as well.

```

FIB-HEAP-INSERT( $H, x$ )
1   $x.degree = 1$ 
2   $x.p = \text{NIL}$ 
3   $x.child = \text{NIL}$ 
4   $x.mark = \text{FALSE}$ 
5  if  $H.min == \text{FALSE}$ 
6      Create a root list for  $H$  containing just  $x$ .
7       $H.min = x$ 
8  else insert  $x$  into  $H$ 's root list
9      if  $x.key < H.min.key$ 
10          $H.min = x$ 
11   $H.n = H.n + 1$ 

```

**Minimum** Just follow the  $H.min$  pointer and you're home safe.

**Extract-Min** This is the most complicated and expensive of the mergeable heap procedures, since it will be doing the work of actually consolidating the trees in the list. Most other procedures put off this work so that it can be done when using Extract-Min. This operation can be done in  $O(\lg n)$  time.

```

FIB-HEAP-EXTRACT-MIN( $H$ )
1   $z.min = H.min$ 
2  if  $z \neq \text{NIL}$ 
3      for each child  $x$  of  $z$ 
4          add  $x$  to the root list of  $H$ 
5           $x.p = \text{NIL}$ 
6      remove  $z$  from the root list of  $H$ 
7      if  $z == z.right$ 
8           $H.min = \text{NIL}$ 
9      else  $H.min = z.right$ 
10     CONSOLIDATE( $H$ )
11      $H.n = H.n - 1$ 
12 return  $z$ 

```

Notice that  $D(H.n)$  here will calculate the upper bound on the degree.

CONSOLIDATE( $H$ )

```

1  let  $A[0..D(H.n)]$  be a new array
2  for  $i = 0$  to  $D(H.n)$ 
3       $A[i] = \text{NIL}$ 
4  for each node  $w$  in the root list of  $H$ 
5       $x = w$ 
6       $d = x.degree$ 
7      while  $A[d] \neq \text{NIL}$ 
8           $y = A[d]$  // another node with the same degree as  $x$ 
9          if  $x.key > y.key$ 
10             exchange  $x$  with  $y$ 
11             FIB-HEAP-LINK( $H, y, x$ )
12              $A[d] = \text{NIL}$ 
13              $d = d + 1$ 
14          $A[d] = x$ 
15   $H.min = \text{NIL}$ 
16  for  $i = 0$  to  $D(H.n)$ 
17      if  $A[i] \neq \text{NIL}$ 
18          if  $H.min == \text{NIL}$ 
19              create a root list for  $H$  containing just  $A[i]$ 
20               $H.min = A[i]$ 
21          else insert  $A[i]$  into  $H$ 's root list
22              if  $A[i].key < H.min.key$ 
23                   $H.min = A[i]$ 

```

FIB-HEAP-LINK( $H, y, x$ )

```

1  remove  $y$  from the root list of  $H$ 
2  make  $y$  a child of  $x$ , incrementing  $x.degree$ 
3   $y.mark = \text{FALSE}$ 

```

**Union** Merging two fibonacci Heaps are done in constant:

FIB-HEAP-UNION( $H_1, H_2$ )

```
1   $H = \text{MAKE-FIB-HEAP}()$ 
2   $H.min = H_1.min$ 
3  Concatenate the root list of  $H_2$  with the root list of  $H$ .
4  if ( $H_1.min == \text{NIL}$ ) or ( $H_2.min \neq \text{NIL}$  and  $H_2.min.key < H_1.min.key$ )
5       $H.min = H_2.min$ 
6   $H.n = H_1.n + H_2.n$ 
7  return  $H$ 
```

**DecreaseKey** We can decrease the key of any node using this method, it runs in  $O(1)$  time.

FIB-HEAP-DECREASE-KEY( $H, x, k$ )

```
1  if  $k > x.key$ 
2      error new key is greater than current key"
3   $x.key = k$ 
4   $y = x.p$ 
5  if  $y \neq \text{NIL}$  and  $x.key < y.key$ 
6      CUT( $H, x, y$ )
7      CASCADING-CUT( $H, y$ )
8  if  $x.key < H.min.key$ 
9       $H.min = x$ 
```

CUT( $H, x, y$ )

```
1  remove  $x$  from the child list of  $y$ , decrementing  $y.degree$ 
2  add  $x$  to the root list of  $H$ 
3   $x.p = \text{NIL}$ 
4   $x.mark = \text{FALSE}$ 
```

```

CASCADING-CUT( $H, y$ )
1   $z = y.p$ 
2  if  $z \neq \text{NIL}$ 
3      if  $y.mark == \text{FALSE}$ 
4           $y.mark = \text{TRUE}$ 
5      else CUT( $H, y, z$ )
6          CASCADING-CUT( $H, z$ )

```

**Delete** Since it uses two previously defined functions, the amortized running-time is easily calculated to  $O(\lg n)$ .

```

FIB-HEAP-DELETE( $H, x$ )
1  FIB-HEAP-DECREASE-KEY( $H, x, -\infty$ )
2  FIB-HEAP-EXTRACT-MIN( $H$ )

```

Write something about  $D(n)$  since it's used for all the proofs.

## NP-Completeness

Example of a problem in the  $P$  class is an Euler Tour (a path in a graph that uses all edges exactly once, vertices can be visited multiple times) of a graph, it can be done in  $O(E)$ . An  $NP$  class example that is very similar is a Hamiltonian cycle. A Hamiltonian cycle is a path that visits all vertices once.

We have three classes of problems in this subject:

**P** Problems that are solvable in polynomial time ( $O(n^k)$  for some constant  $k$ .)

**NP** Problems that are verifiable on polynomial time, i.e. if we have a certificate/solution, can we check it in polynomial time. All problems in  $P$  will also be in  $NP$ .

**NP-Hard** A subclass of  $NP$  problems that are “at least as hard as the hardest problems in  $NP$ ”, these cannot be verified in polynomial time.

**NPC** Problems that are both in the set of  $NP$  problems and  $NP$ -hard problems. ( $NP \cap NP$ -Hard)

### Decision problems vs. optimization problems

$NP$ -completeness does not cover optimization problems, only decision problems. We can however use the relationship between optimization and decision problems to gauge if an optimization problem is in fact  $NP$ -complete.

The shortest-path problem is an optimization problem, but can be converted (in polynomial time) to a decision problem if the question is posed like so: “Does a path  $p$  in the graph  $G$  exist with only  $k$  edges?”, then we iterate over  $k$  and will be able to gauge the shortest path problem as a decision problem.

### Reduction

The notion of showing that one problem is no harder or no easier than another problem applies even when both problems are decision problems. This is used in almost all  $NP$ -Completeness proof as follows: Take an instance  $\alpha$  of problem  $A$ , that is, a specific input for the problem  $A$ , so for shortest path we may choose a graph  $G$ , and vertices  $u$  and  $v$  as well as a  $k$ . Make a polynomial time

transformation from  $\alpha$  to instance  $\beta$  of problem  $B$  (which can be decided in polynomial time) with the following characteristics:

1. Transformation takes polynomial time.
2. The answers are the same. The answer for  $\alpha$  is “yes”, iff. the answer for  $\beta$  is “yes”, same for “no”.

Such an algorithm is called a reduction algorithm.

We can now solve any instance of  $A$  in polynomial time by converting  $\alpha$  to  $\beta$  in polynomial time, running the polynomial time decision algorithm for  $B$  and using the answer for  $B$  as the answer for  $A$ .

Since NP-Completeness is usually how showing how hard a problem is we can use polynomial time reduction algorithms in the opposite way to show that a problem is NP-Complete. Lets show that for some problem  $B$  there can be no polynomial time algorithm.

Suppose we have a decision problem  $A$ , which we know that no polynomial time algorithm can exist. Suppose we also have a polynomial time reduction algorithm that can reduce instances of  $A$  into instances of  $B$  instead. Now, suppose otherwise, if  $B$  had a polynomial time algorithm, we would be able to reduce  $A$  to  $B$  and have a polynomial time algorithm for  $A$ , which we assumed could not exist, which is a contradiction.

### **Abstract Problems**

We define the abstract problem  $Q$  to be the binary relationship between an instance in the set  $I$  and a solution. For our shortest path problem, the instance would be a triple of input  $i = (G, u, v)$  and the solution  $s$  would be a series of vertices. Since NP-Completeness is about decision problems, the input would instead be  $i = (G, u, v, k)$  and the output would be  $s = \{0, 1\}$ . Resulting in a decision problem like so  $Path(i) = 1$ (yes) if a path exists in  $G$  between  $u$  and  $v$  using  $k$  vertices. and  $Path(i) = 0$ (no) otherwise. We thus rely on the ability to recast optimization problems as decision problems in order to make decisions about their NP-Completeness.

## Formal Language Framework

$\Sigma$  is an alphabet, a language  $L$  over the alphabet  $\Sigma$  is any combination of symbols from  $\Sigma$ . For instance if  $\Sigma = \{0, 1\}$  we can have  $L = \{0, 1, 10, 11, 101, 110, 111, \dots\}$ . We denote the empty string as  $\epsilon$  and the empty language as  $\emptyset$ , and the language of all strings over  $\Sigma$  as  $\Sigma^*$ . For instance if  $\Sigma = \{0, 1\}$  then  $\Sigma^* = \{\epsilon, 0, 1, 10, 11, 100, 101, 110, 111, 1000, \dots\}$ . Every language  $L$  over  $\Sigma$  is a subset of  $\Sigma^*$ .

We can perform several operations on languages, set operations such as union and intersect, or the complement of a language  $L$  as  $\bar{L} = \Sigma^* - L$ . The concatenation  $L_1 L_2$  of two languages is

$$L = \{x_1 x_2 : x_1 \in L_1 \text{ and } x_2 \in L_2\}.$$

The closure or Kleene star of a language is

$$L^* = \{\epsilon\} \cup L \cup L^2 \cup L^3 \cup \dots,$$

where  $L^k$  is the language obtained by concatenating  $L$  to itself  $k$  times.

## Randomized Algorithms

When talking random variables there are generally 3 kinds:

1. Las Vegas algorithms
2. Monte Carlo algorithms with one-sided error
3. Monte Carlo algorithms with two-sided error

A Las Vegas algorithm is a randomized algorithm that have zero possibility of producing an invalid solution but where the running time is affected by the randomization.

A Monte Carlo algorithm is a randomized algorithm that might produce an incorrect solution. For decisions problems these can be one-sided or two-sided. A one sided algorithm is always correct for one of the answer (yes/no) but might be wrong on the other one. If it is two-sided then it might be wrong on both answers.

### Markov & Chebyshev's inequalities

**Markov inequality** Let  $Y$  be a random variable assuming only non-negative values. Then for all  $t \in \mathbb{R}^+$ ,

$$\Pr[Y \geq t] \leq \frac{E[Y]}{t}.$$

Equivalently,

$$\Pr[Y \geq kE[Y]] \leq \frac{1}{k}.$$

**Proof** Define a function  $f(y)$ :

$$f(y) = \begin{cases} 1 & \text{iff } y \geq t \\ 0 & \text{otherwise.} \end{cases}$$

Then  $\Pr[Y \geq t] = E[f(y)]$ . Since  $f(y) \leq y/t$  for all  $y$ ,

$$E[f(Y)] \leq E\left[\frac{Y}{t}\right] = \frac{E[Y]}{t},$$

and the theorem follows. □

**Chebyshevs inequality** Let  $X$  be a random variable with expectation  $\mu_X$  and a standard deviation of  $\sigma_X$ . Then for any  $t \in \mathbb{R}^+$ ,

$$\Pr[|X - \mu_X| \geq t\sigma_X] \leq \frac{1}{t^2}$$

**Proof** Note that

$$\Pr[|X - \mu_X| \geq t\sigma_X] = \Pr[(X - \mu_X)^2 \geq t^2\sigma_X^2]$$

The random variable  $Y = (X - \mu_X)^2$  has expectation  $\sigma_X^2$ , and applying the Markov inequality to  $Y$  bounds this probability from above by  $1/t^2$ .  $\square$

Write about lazy select or randomized quicksort

## Exact Exponential Algorithms & Fixed-Parameter Tractable Problems

### Exact Exponential Algorithms

The  $O^*$  notation is similar to the  $O$  notation, except it will suppress running-times of polynomial time. This means that factors that are not exponential are suppressed. For example  $O(kn^k k^n) = O(n^k k^n)$  but we have  $O^*(kn^k k^n) = O^*(k^n)$ .

Roughly speaking, parameterized complexity seeks the possibility of obtaining algorithms whose running time can be bounded by a polynomial function of the input length and, usually, an exponential function of the parameter.

This section is basically about algorithms that solve problems in the NP group in exponential time but give the correct result and not just an approximation.

### Fixed-Parameter Tractable Problems

#### CNF satisfiability

**Parameter “Clause Size”** The maximum number of  $k$  literals a clause may contain. For  $k = 2$  (2-CNF satisfiability) the running time is polynomial time solvable, however for  $k = 3$  (3-CNF satisfiability) is NP-Complete.

**Parameter “Number of Variables”** The number  $n$  of different variables allowed in the formula. Since there is essentially  $2^n$  different truth assignments, the problem can be solved in that number of steps, seeing that the result of each assignment can be calculated in a number of steps equal to the Number of clauses.

**Parameter “Number of Clauses”** If the number of clauses in a formulae is bounded from above by  $m$ , the CNF problem can be solved in  $1.24^m$  steps.

**Parameter “Formula Length”** If the total length (counting the number of literal occurrences in the formula) of the formula  $F$  is bounded by above by  $\ell = |F|$ , then the problem can be solved in  $1.08^\ell$  steps.

## Approximation Algorithms

### Performance Ratios and Schemes

An algorithm for a problem have an approximation ratio of  $\rho(n)$  if, for any input of size  $n$ , the cost  $C$  of a solution produced by the algorithm is within a factor of  $\rho(n)$  of the cost  $C^*$  of an optimal solution:

$$\max\left(\frac{C}{C^*}, \frac{C^*}{C}\right) \leq \rho(n).$$

If an algorithm achieves an approximation ratio of  $\rho(n)$ , we call it a  $\rho(n)$ -approximation algorithm. These notions apply to both cost-minimization and cost-maximization problems.

For a maximization problem,  $0 < C \leq C^*$ , and the ratio  $C^*/C$  gives the factor by which the cost of an optimal solution is larger than the cost of the approximation solution.

Similarly, for a minimization problem,  $0 < C^* \leq C$ , and the ratio  $C/C^*$  gives the factor by which the cost of the approximate solution is larger than the cost of an optimal solution.

Because we assume the costs are always positive, the ratios are always well defined, the ratio of an algorithm is never less than 1, since  $C/C^* \leq 1$  implies  $C^*/C \geq 1$ . Therefore a 1-approximation algorithm produce an optimal solution and an approximation algorithm with a large approximation ratio may return a solution far worse than optimal.

Below some schemes are outlined which allow us to give a value  $\epsilon$  along with the instance of the problem and achieve an approximation that have a quality depending on the value.

**Approximation Scheme** for an optimization problem is an approximation algorithm that takes as input, not only an instance of the problem, but also a value  $\epsilon > 0$  such that for any fixed  $\epsilon$  the scheme is a  $(1 + \epsilon)$ -approximation algorithm.

**Polynomial-Time Approximation Scheme** is an approximation scheme if for any fixed  $\epsilon > 0$ , the scheme runs in polynomial time in the size  $n$  of it's input instance. The running time of such a scheme can increase rapidly as

$\epsilon$  decreases. For example, the running time of a polynomial-time approximation scheme might be  $O(n^{(2/\epsilon)})$ . Ideally, if  $\epsilon$  decrease by a constant factor, the running time to achieve the desired approximation should not increase by more than a constant factor. (Not necessarily by the same factor  $\epsilon$  was decreased with.)

**Fully Polynomial-Time Approximation Scheme** means the approximation algorithm runs in polynomial time in both  $1/\epsilon$  and the size  $n$  of the input instance. I.e.  $O((1/\epsilon)^2 n^3)$ . With such a scheme, a constant factor decrease in  $\epsilon$  comes with a constant factor increase in runningtime.

### Vertex Cover example

A Vertex Cover of an undirected graph  $G = (V, E)$  is a subset  $V' \subseteq V$  such that if  $(u, v)$  is an edge of  $G$ , then either  $u \in V'$  or  $v \in V'$  or both. The size of a vertex cover is the number of vertices in it.

The Vertex Cover Problem is to find a vertex cover of minimum size in a given undirected graph, this is an optimization version of an NP-Complete decision problem.

An approximation algorithm that will find a cover that is no more than twice the size of the optimal cover is written here:

APPROX-VERTEX-COVER( $G$ )

```

1   $C = \emptyset$ 
2   $E' = E$ 
3  while  $E' \neq \emptyset$ 
4      let  $(u, v)$  be an arbitrary edge of  $E'$ 
5       $C = C \cup \{u, v\}$ 
6      remove from  $E$  every edge incident on either  $u$  or  $v$ 
7  return  $C$ 
```

The above algorithm runs in  $O(V + E)$ .

Figure 6: Example run of the Approx-Vertex-Cover algorithm.

**Theorem 35.1** Approx-Vertex-Cover is a polynomial-time 2-approximation algorithm.

**Proof** It is already shown that the algorithm is a polynomial time algorithm.

The set  $C$  of vertices return must be a vertex cover since it loops until every edge in  $G.E$  have been covered by some vertex.

To see that the algorithm returns a vertex cover of at most twice the size of an optimal cover, let  $A$  denote the set of edges that line 4 selects. To cover all the edges in  $A$ , any vertex cover, in particular the optimal vertex cover  $C^*$ , must include at least one endpoint of each edge in  $A$ . No two edges share endpoints since when an edge is picked, all edges incident on its endpoints are removed. Thus no two edges in  $A$  are covered by the same vertex from  $C^*$ , and we have the lower bound

$$|C^*| \geq |A|$$

on the size of an optimal vertex cover. Each execution of line 4 picks an edge which neither of its endpoints are already in  $C$ , yielding an upper bound on the size of the vertex cover returned

$$|C| = 2|A|$$

Combining the two bounds gives

$$\begin{aligned} |C| &= 2|A| \\ &\leq 2|C^*| \end{aligned}$$

thereby proving the theorem. □
